GLEAM v3.7 Datasets

1. – GENERAL

The Global Land Evaporation Amsterdam Model\(^1\,\,^2\) (GLEAM) is a set of algorithms that separately estimate the different components of terrestrial evaporation (i.e. 'evapotranspiration') based on satellite observations: transpiration (\(E_t\)), interception loss (\(E_i\)), bare-soil evaporation (\(E_b\)), snow sublimation (\(E_s\)) and open-water evaporation (\(E_w\)). Intermediate outputs of the model include: potential evaporation (\(E_p\)), root-zone soil moisture (\(SM_{root}\)), surface soil moisture (\(SM_{surf}\)), and evaporative stress (\(S\)).

The rationale of the method is to maximize the recovery of information about evaporation contained in the available data stack of climatic and environmental observations from space. A Priestley and Taylor equation calculates \(E_p\) based on observations of surface net radiation and near-surface air temperature\(^3\). Potential evaporation estimates are converted into actual evaporation based on the multiplicative, evaporative stress factor \(S\). The derivation of \(S\) is based on microwave observations of the vegetation optical depth – used as a proxy for the vegetation water content – and simulations of root-zone soil moisture. The latter is calculated using a multi-layer running water balance that describes the infiltration of observed precipitation through the vertical soil profile. To correct for random forcing errors, microwave observations of surface soil moisture are assimilated into the soil profile. Interception loss is calculated separately based on the Gash analytical model of rainfall interception\(^4\,\,^5\) driven by observations of precipitation and both vegetation and rainfall characteristics. Estimates of actual evaporation for regions covered by ice and/or snow are derived using a Priestley and Taylor equation adapted for ice and super-cooled waters. For a detailed description, the reader is directed to Miralles et al. (2011)\(^1\,\,^2\) and Martens et al. (2017)\(^6\).

The version 3 of the model includes:

1. A new data assimilation scheme that was validated in Martens et al. (2017)\(^6\).
2. An updated water-balance module that describes the infiltration rates as a function of the vertical gradient in soil moisture\(^6\).
3. Updated evaporative stress functions (based on experimental evidence) that combine the vegetation optical depth and the root-zone soil moisture estimates\(^6\).

As of 20th of June 2022, two datasets produced using GLEAM v3 are currently available at the www.gleam.eu server: GLEAM v3.7a and GLEAM v3.7b.

2. – DATA CHARACTERISTICS

The two datasets available on this server differ only in their forcing and temporal coverage:

1. **GLEAM v3.7a**: a global dataset spanning the 43-year period 1980–2022. The dataset is based on reanalysis radiation and air temperature, a combination of gauge-based,
reanalysis and satellite-based precipitation, and satellite-based vegetation optical depth (see Table 1).

2. **GLEAM v3.7b**: a global dataset spanning the 20-year period 2003–2022. The dataset is largely driven by satellite data (see Table 1).

Table 1 provides more information on the forcing variables used to produce these datasets. All GLEAM datasets are provided on a 0.25° x 0.25° latitude–longitude grid and with a daily temporal resolution.

**Table 1: Overview of forcing datasets.**

<table>

* Note that the surface soil moisture is assimilated into GLEAM thus is not a forcing variable as such.

3. – FILE ORGANISATION

Datasets are organised in netcdf files. There is one netcdf file per variable and per year, and they are stored as a **3D array with dimensions n-days x 720 x 1440** (n-days is the number of days in the corresponding year). Therefore, the first cell corresponds to the 1st of January of the corresponding year, and it is centered at latitude 89.875 and longitude -179.875. The following 10 variables are available:

1. **E** - Actual evaporation [mm/day]
2. **Ep** - Potential evaporation [mm/day]
3. **Ei** - Interception loss [mm/day]
4. **Eb** - Bare-soil evaporation [mm/day]
5. **Es** - Snow sublimation [mm/day]
6. **Et** - Transpiration [mm/day]
7. **Ew** - Open-water evaporation [mm/day]
8. **S** - Evaporative stress factor [-]
9. **SMroot** - Root-zone soil moisture [m3/m3]
10. **SMsurf** - Surface soil moisture; 0-10 [m3/m3]
Note that by definition: \( E = E_t + E_b + E_w + E_i + E_s \) and \( S = E/Ep \). Missing values in the files are masked with –999.

Next to the daily data, temporally aggregated files (monthly and yearly) are also available. There is one netcdf file per variable with the entire record at either monthly (dimensions \( n\text{-days} \times 720 \times 1440 \)), or yearly (dimensions \( n\text{-days} \times 720 \times 1440 \)) temporal resolution, date stamps are set to roughly the end (i.e. the end of the aggregation period) of the month or year, respectively.

4. – DATA POLICY

Datasets are freely available and can be downloaded from this server. Use of the data is however subject to the following terms and conditions:

1. **Acknowledgements.** Whenever GLEAM datasets are used in a scientific publication, the following references should be cited:
   

2. **Scientific use only.** GLEAM datasets will not be used for commercial purposes.

5. – FINAL REMARKS

1. The reader is referred to the **references below for more detailed information** about the model.
2. Please consider having a look at our list of frequently asked questions and answers at [www.gleam.eu](http://www.gleam.eu).
3. Any feedback about the datasets and/or website is highly appreciated and can be sent through email to [info@gleam.eu](mailto:info@gleam.eu) and/or to Akash Koppa (Postdoctoral Researcher, Hydro-Climate Extremes Lab, Ghent University, Belgium) at [akash.koppa@ugent.be](mailto:akash.koppa@ugent.be).
