Abrupt transitions and large deviations in geophysical turbulent flows

F. BOUCHET (CNRS) – ENS-Lyon and CNRS

May 2014 – Hamburg
Random changes of flow topology in the 2D Navier-Stokes equations: E. Simonnet (INLN-Nice) (ANR Statocean)

Asymptotic stability and inviscid damping of the 2D-Euler equations: H. Morita (Tokyo university) (ANR Statflow)

Large deviations, instantons non-equilibrium phase transition for quasi-geostrophic turbulence: J. Laurie (Post-doc ANR Statocean), O. Zaboronski (Warwick Univ.)

Stochastic Averaging and Jet Formation in Geostrophic Turbulence: C. Nardini and T. Tangarife (ENS-Lyon)

Phase transitions in rotating tank experiments: J. Sommeria (LEGI-Grenoble) and M. Mathur (Post-doc ANR Statocean, now in India)
Jupiter’s Zonal Jets
We look for a theoretical description of zonal jets

Jupiter’s atmosphere

Jupiter’s zonal winds (Voyager and Cassini, from Porco et al 2003)

How to theoretically predict such a velocity profile?
Has One of Jupiter’s Jets Been Lost?
We look for a theoretical description of zonal jets

The white ovals appeared in 1939-1940 (Rogers 1995). Following an instability of the zonal jet?
Abrupt Climate Changes
Long times matter

Temperature versus time: Dansgaard–Oeschger events (S. Rahmstorf)

- What is the dynamics and probability of abrupt climate changes?
- Predict attractors, transition pathways and probabilities.
- Study a hierarchy of models of ocean circulation and of turbulent atmospheres.
Transitions between blocked and zonal states

Y. Tian and others

Random Transitions in Turbulence Problems
Magnetic Field Reversal (Turbulent Dynamo, MHD Dynamics)

In turbulent flows, transitions from one attractor to another often occur through a predictable path.

- Compute attractors, transition pathways and probabilities.
The Main Issues

- How to characterize and predict the attractors in turbulent geophysical flows?
- In case of multiple attractors, can we compute their relative probability?
- Can we compute the transition pathways and the transition probabilities?
Large Deviation Theory and Statistical Mechanics

- Probability of an order parameter $p[\omega]$ and large deviations

$$p[\omega](x, \sigma, t) = \langle \delta (\omega(x, t) - \sigma) \rangle$$

$$\mathcal{P}[p] \sim \epsilon \ll 1 \quad C e^{-\mathcal{F}[p]/\epsilon}.$$ 

- For equilibrium systems, $\mathcal{F}$ is the free energy, and $\epsilon = k_B T / N$.
- Computing $\mathcal{F}$ “solves” the dynamics (most probable state, fluctuations, phase transitions).
- The large deviation function $\mathcal{F}$ can be computed from the dynamics (Macroscopic fluctuation theory, instanton theory).
- Large deviation theory extends statistical mechanics tools to non-equilibrium systems.
The Main Mathematical Questions

- How to characterize and predict attractors in turbulent geophysical flows?
- When is Freidlin–Wentzell theory relevant for turbulent flows?
- Large deviation results beyond Freidlin–Wentzell theory?
The Barotropic Quasi-Geostrophic Equations

- The simplest model for geostrophic turbulence.
- Quasi-Geostrophic equations with random forces
  \[
  \frac{\partial q}{\partial t} + \mathbf{v} \cdot \nabla q = \nu \Delta \omega - \alpha \omega + \sqrt{2\sigma} f_s,
  \]
  with \( q = \omega + \beta y \).
- \( \beta = 0 \): the two–dimensional stochastic Navier-Stokes equations.
Outline

1. The 2D Navier–Stokes Eqs
   - The equilibrium statistical mechanics
   - Non equilibrium phase transitions
   - Other close to equilibrium bifurcations in turbulent flows
     (F.B., M. Mathur, E. Simonnet, and J. Sommeria)

2. 2D Euler and Quasi-Geostrophic Langevin dynamics: Large Deviations and Instantons.
   - Langevin dynamics, time reversal symmetry and large deviations.
   - Instantons for Langevin quasi-geostrophic dynamics (F.B., J. Laurie, and O. Zaboronski).
   - Non-Equilibrium Instantons for the 2D Navier–Stokes equations (F.B. and J. Laurie)

3. Stochastic averaging and jet formation in geostrophic turbulence.
   - The stochastic quasi-geostrophic equations.
   - Stochastic averaging (with C. Nardini and T. Tangarife)

F. Bouchet, CNRS–ENSL

Phase transitions in geophysical fluid dynamics.
Outline

1. The 2D Navier–Stokes Eqs
   - The equilibrium statistical mechanics
   - Non equilibrium phase transitions
   - Other close to equilibrium bifurcations in turbulent flows (F.B., M. Mathur, E. Simonnet, and J. Sommeria)

2. 2D Euler and Quasi-Geostrophic Langevin dynamics: Large Deviations and Instantons.
   - Langevin dynamics, time reversal symmetry and large deviations.
   - Instantons for Langevin quasi-geostrophic dynamics (F.B., J. Laurie, and O. Zaboronski).
   - Non-Equilibrium Instantons for the 2D Navier–Stokes equations (F.B. and J. Laurie)

3. Stochastic averaging and jet formation in geostrophic turbulence.
   - The stochastic quasi-geostrophic equations.
   - Stochastic averaging (with C. Nardini and T. Tangarife)
The 2D Euler Equations

- 2D Euler equations:

\[ \frac{\partial \omega}{\partial t} + \mathbf{v}[\omega] \cdot \nabla \omega = 0, \]

Vorticity \( \omega = (\nabla \wedge \mathbf{v}) \cdot \mathbf{e}_z \). Stream function \( \psi: \mathbf{v} = \mathbf{e}_z \times \nabla \psi, \omega = \Delta \psi. \)

- Conservative dynamics - Hamiltonian (non canonical) and time reversible.
Equilibrium Large Deviation: Macrostate Entropy
The most probable vorticity field (Miller–Robert–Sommeria theory)

- A probabilistic description of the vorticity field $\omega$: $\rho(x, \sigma)$ is the local probability to have $\omega(x) = \sigma$ at point $x$.
- A measure of the number of microscopic field $\omega$ corresponding to a probability $\rho$ (Liouville and Sanov theorems):

$$\text{Macrostate entropy} : \mathcal{I}[\rho] \equiv - \int \mathcal{D} \! d\sigma \rho \log \rho.$$ 

- The microcanonical variational problem (MVP):

$$S(E) = \sup_{\{\rho | \mathcal{N}[\rho] = 1\}} \{ \mathcal{I}_2[\rho] | \mathcal{E}[\omega] = E \text{ and } D(\sigma) = d(\sigma) \} \text{ (MVP).}$$

- Critical points are steady solutions of the 2D Euler equations:

$$\overline{\omega} = f_d(\beta \psi).$$
Statistical Equilibria for the 2D-Euler Eq. (torus)

A second order phase transition.

Outline

1. The 2D Navier–Stokes Eqs
   - The equilibrium statistical mechanics
   - Non equilibrium phase transitions

2. 2D Euler and Quasi-Geostrophic Langevin dynamics: Large Deviations and Instantons.
   - Langevin dynamics, time reversal symmetry and large deviations.
   - Instantons for Langevin quasi-geostrophic dynamics (F.B., J. Laurie, and O. Zaboronski).
   - Non-Equilibrium Instantons for the 2D Navier–Stokes equations (F.B. and J. Laurie)

3. Stochastic averaging and jet formation in geostrophic turbulence.
   - The stochastic quasi-geostrophic equations.
   - Stochastic averaging (with C. Nardini and T. Tangarife)
The 2D Stochastic-Navier-Stokes (SNS) Equations

- The simplest model for two dimensional turbulence.
- Navier Stokes equations with random forces

\[
\frac{\partial \omega}{\partial t} + \mathbf{v} \cdot \nabla \omega = \nu \Delta \omega - \alpha \omega + \sqrt{\sigma} \mathbf{f_s},
\]

where \(\omega = (\nabla \wedge \mathbf{v}) \cdot \mathbf{e}_z\) is the vorticity, \(f_s\) is a random force, \(\alpha\) is the Rayleigh friction coefficient.
Statistical Equilibria for the 2D-Euler Eq. (torus)

A second order phase transition.

Non-Equilibrium Phase Transition (2D Navier–Stokes Eq.)

The time series and PDF of the Order Parameter

\[ \delta = 1.02 \]

\[ \delta = 1.04 \]

Order parameter: \( z_1 = \int dx dy \exp(iy) \omega(x, y) \).

For unidirectional flows \( |z_1| \approx 0 \), for dipoles \( |z_1| \approx 0.6 - 0.7 \)

Outline

1. The 2D Navier–Stokes Eqs
   - The equilibrium statistical mechanics
   - Non-equilibrium phase transitions
   - Other close to equilibrium bifurcations in turbulent flows
     (F.B., M. Mathur, E. Simonnet, and J. Sommeria)

2. 2D Euler and Quasi-Geostrophic Langevin dynamics: Large Deviations and Instantons.
   - Langevin dynamics, time reversal symmetry and large deviations.
   - Instantons for Langevin quasi-geostrophic dynamics (F.B., J. Laurie, and O. Zaboronski).
   - Non-Equilibrium Instantons for the 2D Navier–Stokes equations (F.B. and J. Laurie)

3. Stochastic averaging and jet formation in geostrophic turbulence.
   - The stochastic quasi-geostrophic equations.
   - Stochastic averaging (with C. Nardini and T. Tangarife)
Historical example: Computation by Kramer of Arrhenius’ law for a bistable mechanical system with stochastic noise

\[
\frac{dx}{dt} = -\frac{dV}{dx}(x) + \sqrt{2k_B T}\eta(t) \quad \text{Rate: } \lambda = \frac{1}{\tau} \exp\left(-\frac{\Delta V}{k_B T}\right).
\]

The problem was solved by Kramers (30'). Modern approach: path integral formulation (instanton theory, physicists) or large deviation theory (Freidlin-Wentzell, mathematicians).
Path Integrals for ODE – Onsager Machlup (50’)

- Path integral representation of transition probabilities:
  \[ P(x_T, T; x_0, 0) = \int_{x(0)=x_0}^{x(T)=x_T} e^{-\mathcal{A}_T[x]} \mathcal{D}[x] \]
  
  with \( \mathcal{A}_T[x] = \int_0^T \mathcal{L}[x, \dot{x}] \, dt \) and \( \mathcal{L}[x, \dot{x}] = \frac{1}{2} \left[ \dot{x} + \frac{dV}{dx}(x) \right]^2 \).

- The most probable path from \( x_0 \) to \( x_T \) is the minimizer of
  \[ A_T(x_0, x_T) = \min\{ \mathcal{A}_T[x] | x(0) = x_0 \text{ and } x(T) = x_T \} \].

- We may consider the low temperature limit, using a saddle point approximation (WKB), Then we obtain the large deviation result
  \[ \log P(x_T, T; x_0, 0) \sim -\frac{A_T(x_0, x_T)}{2k_B T}. \]
Time Reversal and Action Duality

- We consider a path $x = \{x(t)\}_{0 \leq t \leq T}$ and its reversed path $x_r = \{I[x(T - t)]\}_{0 \leq t \leq T}$. We have
  \[ \mathcal{A}_T [x_r] = \mathcal{A}_T [x] + 2V(x(T)) - 2V(x(0)). \]

- Transition probabilities of the direct process are related to transition probabilities of the dual process (a generalization of detailed balance).

- This implies that the most probable path to reach a state $x$ (a fluctuation) is the time reversal of a relaxation path starting from $I[x]$ for the dual process (dissipation).

- This is a generalized Onsager-Machlup relation, that justifies generalization of fluctuation-dissipation relations.

- Instantons are the time reversed relaxation paths of the dual process.

F. Bouchet CNRS–ENSL
Phase transitions in geophysical fluid dynamics.
Langevin Dynamics In a General Framework

\[ \frac{\partial q}{\partial t} = \mathcal{F}[q](r) - \alpha \int_D C(r, r') \frac{\delta G}{\delta q(r')} [q] \, dr' + \sqrt{2\alpha \gamma \eta}, \]

- Assumptions: i) \( \mathcal{F} \) verifies a Liouville theorem

\[ \nabla \cdot \mathcal{F} = \int_D \frac{\delta \mathcal{F}}{\delta q(r)} \, dr = 0 \quad \text{(Generalization of } \nabla \cdot \mathcal{F} = \sum_{i=1}^{N} \frac{\partial \mathcal{F}}{\partial q_i} = 0 \text{)} , \]

- ii) The potential \( G \) is a conserved quantity of \( \frac{\partial q}{\partial t} = \mathcal{F}[q](r): \)

\[ \int_D \mathcal{F}[q](r) \frac{\delta G}{\delta q(r)} [q] \, dr = 0. \]

- iii) \( \eta \) a Gaussian process, white in time, with covariance

\[ \mathbb{E}[\eta(r, t)\eta(r', t')] = C(r, r') \delta(t - t'). \]

- For most classical Langevin dynamics:

\[ \mathcal{F}[q](r) = \{q, \mathcal{H}\} \text{ and } G = \mathcal{H}. \]
Langevin Dynamics for the Quasi-Geostrophic Eq.

\[ \frac{\partial q}{\partial t} = \mathbf{v}[q - h] \cdot \nabla q - \alpha \int_D C(r, r') \frac{\delta G}{\delta q(r')} [q] \, dr' + \sqrt{2\alpha \gamma \eta}. \]

- **Assumptions:**
  1. \( \mathcal{F} = -\mathbf{v}[q - h] \cdot \nabla q \) verifies a Liouville theorem.
  2. The potential \( G \) is a conserved quantity of \( \frac{\partial q}{\partial t} = \mathcal{F}[q](r) \)

\[ G = \mathcal{C} + \beta E, \]

with a Casimir functionals

\[ \mathcal{C}_c = \int_D \, dr \, c(q), \]

and energy

\[ \mathcal{E} = -\frac{1}{2} \int_D \, dr \, [q - H\cos(2y)] \psi = \frac{1}{2} \int_D \, dr \, \nabla \psi^2. \]
Tricritical Points
Bifurcation from a second order to a first order phase transition

Tricritical point corresponding to the normal form

\[ s(m) = -m^6 - \frac{3b}{2} m^4 - 3am^2. \]
A Quasi-Geostrophic Potential with A Tricritical Point

\[ \mathcal{G} = \left(1 - \varepsilon\right) \frac{1}{2} \int \mathcal{D}r \left[ q - H \cos(2y) \right] \psi + \int \mathcal{D}r \left[ \frac{q^2}{2} - \frac{a_4 q^4}{4} + \frac{a_6 q^6}{4} \right] \quad \text{with} \quad h(y) = H \cos(2y). \]

- There is a tricritical transition (transition from first order to second order) close to \( \varepsilon = 0 \) and \( a_4 = 0 \) for small \( H \).
- Close to the transition the stochastic dynamics can be reduced to a two-degrees of freedom stochastic dynamics, which is a gradient dynamics with potential

\[ G(A, B) = -\frac{H^2}{3} + \varepsilon \left[ A^2 + B^2 \right] - \frac{3a_4}{2} \left[ A^2 + B^2 \right]^2 + \frac{a_6}{6} \gamma \left[ A^2 + B^2 \right]^3 + \frac{5\pi}{144} a_6 H^2 \left( A^2 - B^2 \right)^2. \]

- And the potential vorticity field is

\[ q(y) \simeq A \cos(y) + B \sin(y). \]
The reduced potential and one instanton/relaxation path.
Bistability for the Langevin Quasi-Geostrophic Eq.

The reduced potential and one instanton/relaxation path.
Conclusion for Phase Transitions of the Langevin Quasi-Geostrophic Eq.

- For this turbulent dynamics, we can predict the phase diagram (a tricritical point). For a range of parameter, we have first order phase transitions.
- Using large deviations, we can compute transition probabilities.
- We can compute the transition rate between two attractors.
- Most transitions concentrate close to the optimal one, it is describe by an instanton that is easily computed.
- Sufficiently close to the tricritical point, the dynamics reduces to a two degrees of freedom stochastic dynamics.
The 2D Navier–Stokes Eqs

2D Euler and Quasi-Geostrophic Langevin dynamics.

Stochastic averaging for geostrophic jets.

Phase transitions in geophysical fluid dynamics.
2D Stochastic Navier-Stokes Eq. and 2D Euler Steady States

\[ \frac{\partial \omega}{\partial t} + \mathbf{v} \cdot \nabla \omega = \nu \Delta \omega - \alpha \omega + \sqrt{2\alpha} f_s \]

- This is no more a Langevin dynamics.
- Time scale separation: magenta terms are small.
**Instantons: Maximum Likelihood Paths**

- Most trajectories that lead to a rare event follow the easiest path.
- **Large deviation theory:** instantons as minimum action paths.

### 2D Navier-Stokes equations

- **(time: 10 000)** (PRL)
- **Goal:** predict attractors, transition pathways and probabilities.
- **Instanton computations** will predict them when it is not possible to do that using direct numerical simulations.

### Numerical instanton

- **(time of order 1)** (J. Stat. Phys.)

---

**F. Bouchet, CNRS-ENSL**

**Phase transitions in geophysical fluid dynamics.**
Instanton in Turbulent Flows: Conclusions

- For some restricted classes of force spectrum (Langevin dynamics), we can solve completely the problem (compute the large deviation functionals, fluctuation paths, transition probabilities, instantons, and so on).
- This is usually not the case. Then we have partial answers only. We can 1) rely on equilibrium large deviation and test empirically their interest for slightly non equilibrium situations 2) compute instantons numerically 3) We have few more cases with explicit instanton solutions.
- A lot is still to be understood.
- More can be done theoretically in the inertial limit.
Outline

1. The 2D Navier–Stokes Eqs
   - The equilibrium statistical mechanics

Averaging out the Turbulence

\[
\frac{\partial q}{\partial t} + \mathbf{v} \cdot \nabla q = \nu \Delta \omega - \alpha \omega + \sqrt{2\alpha} f_s.
\]

- \( P[q] \) is the PDF for the Potential Vorticity field \( q \) (a functional). **Fokker–Planck equation:**

\[
\frac{\partial P}{\partial t} = \int \! \! d\mathbf{r} \frac{\delta}{\delta q(\mathbf{r})} \left\{ \left[ \mathbf{v} \cdot \nabla q - \nu \Delta \omega + \alpha \omega + \int \! \! d\mathbf{r}' C(\mathbf{r}, \mathbf{r}') \frac{\delta}{\delta q(\mathbf{r})} \right] P \right\}.
\]

- **Time scale separation. We decompose into slow (zonal flows) and fast variables (eddy turbulence)**

\[
q_z(y) = \langle q \rangle \equiv \frac{1}{2\pi} \int_{\mathcal{D}} \! \! dx \, q \text{ and } q = q_z + \sqrt{\alpha} q_m.
\]

- **Stochastic reduction (Van Kampen, Gardiner, …) using the time scale separation.**
- **We average out the turbulent degrees of freedom.**
A New Fokker–Planck Equation for the Zonal Jets

- $R[q_z]$ is the PDF to observe the Zonal Potential Vorticity $q_z$:

$$\frac{1}{\alpha} \frac{\partial R}{\partial t} = \int dy_1 \frac{\delta}{\delta q_z(y_1)} \left\{ \left[ \frac{\partial}{\partial y} \mathbb{E}_q z \langle \nu_{m,y} q_m \rangle + \omega_z(y_1) - \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2}(y_1) + \right. \right.$$  

$$\left. + \int dy_2 C_z(y_1, y_2) \frac{\delta}{\delta q_z(y_2)} \right] R \right\}.$$

- This new Fokker–Planck equation is equivalent to the stochastic dynamics

$$\frac{1}{\alpha} \frac{\partial q_z}{\partial t} = - \frac{\partial}{\partial y} \mathbb{E}_q z \langle 
u_{m,y} q_m \rangle - \omega_z + \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2} + \eta_z,$$

with $\langle \eta_z(y, t) \eta_z(y', t') \rangle = C_z(y, y') \delta(t - t')$. 

F. Bouchet \hspace{1cm} CNRS–ENSL

Phase transitions in geophysical fluid dynamics.
The Deterministic Part and the Quasilinear Approximation

Deterministic quasilinear dynamics

\[ \frac{1}{\alpha} \frac{\partial q_z}{\partial t} = F[q_z] - \omega_z + \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2}. \]

- \( F[q_z] = -\frac{\partial}{\partial y} \mathbb{E}_{q_z} \langle v_{m,y} q_m \rangle. \) The average of the Reynolds stress is over the Ornstein-Uhlenbeck process for the linearized dynamics close to the current zonal flow \( U(y) \) and vorticity profile \( q_z \), with random forces:

\[ \partial_t q_m + U(y) \frac{\partial q_m}{\partial x} + v_{m,y} \frac{\partial q_z}{\partial y} = \nu \Delta q_m - \alpha \omega_m + f_s. \]

- We identify SSST by Farrell and Ioannou (JAS, 2003); quasilinear theory by Bouchet (PRE, 2004); CE2 by Marston, Conover and Schneider (JAS, 2008); Sreenivasan and Young (JAS, 2011).
The 2D Navier–Stokes Eqs
2D Euler and Quasi-Geostrophic Langevin dynamics.

Farid Ait Chaalal and Tapio Schneider (Caltech and ETH Zurich).

• The qualitative structure of a fast rotating Earth troposphere is well approximated by quasilinear dynamics.
The Stochastic Dynamics of the Zonal Jet
Beyond the deterministic quasilinear approximation: the noise term

- We can now go further. What is the effect of the noise term?
  
  \[
  \frac{1}{\alpha} \frac{\partial q_z}{\partial t} = F[q_z] - \omega_z + \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2} + \eta_z. \]

- \( R[q_z] \) is the PDF to observe the Zonal Potential Vorticity \( q_z \):
  
  \[
  \frac{1}{\alpha} \frac{\partial R}{\partial t} = \int dy_1 \frac{\delta}{\delta q_z(y_1)} \left\{ \left[ \frac{\partial}{\partial y} E_{q_z} \langle v_{m,y} q_m \rangle + \omega_z(y_1) - \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2}(y_1) + \right. \right. 
  
  + \int dy_2 C_z(y_1, y_2) \frac{\delta}{\delta q_z(y_2)} \left. \right] R \right\}. \]

- This equation describes the zonal jet statistics and not only the mean zonal flow.
- This statistics can be nearly Gaussian, but can also be strongly non-Gaussian.
Random Transitions in Turbulence Problems
Magnetic Field Reversal (Turbulent Dynamo, MHD Dynamics)

In turbulent flows, transitions from one attractor to another often occur through a predictable path.

- Compute attractors, transition pathways and probabilities.
Multiple Attractors Do Exist for the Barotropic QG Model

Two attractors for the same set of parameters.

What is the dynamics for the transition? What is the transition rate?

Figure by P. Ioannou (Farrell and Ioannou).

- Two attractors for the mean zonal flow for one set of parameters.
- What is the dynamics for the transition? What is the transition rate?
Work in Progress: Zonal Flow Instantons
Onsager Machlup formalism (50’). Statistical mechanics of histories

\[
\frac{1}{\alpha} \frac{\partial q_z}{\partial t} = F[q_z] - \omega_z + \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2} + \eta_z.
\]

- Path integral representation of transition probabilities:

\[
P(q_z,0,q_z,T,T) = \int_{q(0)=q_z,0}^{q(T)=q_z,T} \mathcal{D}[q_z] \exp(-\mathcal{S}[q_z]) \text{ with}
\]

\[
\mathcal{S}[q_z] = \frac{1}{2} \int_0^T dt \int dy_1 dy_2 \left[ \frac{\partial q_z}{\partial t} - F[q_z] + \omega_z - \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2} \right] (y_1) C_Z(y_1,y_2) \left[ \frac{\partial q_z}{\partial t} - F[q_z] + \omega_z - \frac{\nu}{\alpha} \frac{\partial^2 q_z}{\partial y^2} \right] (y_2).
\]

- Instanton (or Freidlin-Wentzel theory): the most probable path with fixed boundary conditions

\[
S(q_z,0,q_z,T,T) = \min_{\{q_z|q_z(0)=q_z,0 \text{ and } q_z(T)=q_z,T\}} \{\mathcal{S}[q_z]\}.
\]
Outline

1. The 2D Navier–Stokes Eqs
   - The equilibrium statistical mechanics
   - Non equilibrium phase transitions
   - Other close to equilibrium bifurcations in turbulent flows (F.B., M. Mathur, E. Simonnet, and J. Sommeria)

2. 2D Euler and Quasi-Geostrophic Langevin dynamics: Large Deviations and Instantons.
   - Langevin dynamics, time reversal symmetry and large deviations.
   - Instantons for Langevin quasi-geostrophic dynamics (F.B., J. Laurie, and O. Zaboronski).
   - Non-Equilibrium Instantons for the 2D Navier–Stokes equations (F.B. and J. Laurie)

3. Stochastic averaging and jet formation in geostrophic turbulence.
   - The stochastic quasi-geostrophic equations.
   - Stochastic averaging (with C. Nardini and T. Tangarife)
The Real Issue was to Cope with UltraViolet Divergences
We have proven that they are no such divergences

\[
\partial_t q_m + U(y) \frac{\partial q_m}{\partial x} + v_{m,y} \frac{\partial q_z}{\partial y} = \nu \Delta q_m - \alpha \omega_m + \sqrt{2f_s}
\]

- We need to prove that the Gaussian process has an invariant measure which is well behaved in the limit \( \nu \to 0 \), and \( \alpha \to 0 \).
- This is true because of inviscid damping of the Quasi-Geostrophic or Euler dynamics.
- The result is based on asymptotics of the linearized equations:

\[
v_{m,x}(y, t) \sim \frac{v_{m,x,\infty}(y)}{t} \exp(-ikU(y)t) \quad \text{and} \quad v_{m,y}(y, t) \sim \frac{v_{m,y,\infty}(y)}{t^2} \exp(-ikU(y)t).
\]

Stochastic averaging for the barotropic Quasi-Geostrophic equation leads to a non-linear Fokker-Planck equation.

This Fokker-Planck equation predicts the Reynolds stress and jet statistics. Related to Quasilinear theory and SSST.

For some parameters, multiple attractors are observed.

Path integral, instanton and large deviation theories can predict rare transitions between attractors.

The 2D Navier–Stokes Eqs
2D Euler and Quasi-Geostrophic Langevin dynamics.
Stochastic averaging for geostrophic jets.

Numerical Computation of Rare Events and Large Deviations
Computation of least action paths (instantons) and/or multilevel splitting

Multilevel-splitting: Ginzburg-Landau transitions (with E. Simonnet and J. Rolland)

2D Navier-Stokes instantons (with J. Laurie)

Rare events and their probability can now be computed numerically in complex dynamical systems.
Summary and Perspectives

- Non-equilibrium statistical mechanics and large deviation theory apply to GFD turbulence.

Ongoing projects and perspectives:
- Large deviations and non-equilibrium free energies for particles with long range interactions (with K. Gawedzki, and C. Nardini).
- Microcanonical measures for the Shallow Water equations (with M. Potters and A. Venaille).
- Rare events, large deviations, and extreme heat waves in the atmosphere (with J. Wouters).
